

Outdoor Fix — Milestone 3 Progress Report

Developer reference | prepared by Hanzalah

Status: in progress. What's built below has been verified live, end to end — not just reviewed in code. What isn't built yet is listed honestly in Section 3, not glossed over.

1. Summary

Milestone 3 (Risk Assessment) is in progress, not yet complete. The scoring engine, the affordability check, apartment auto-decline, and Plaid bank verification are all built and confirmed working live. A meaningful part of the plan's original scope — third-party identity and employment checks, a background-check provider, deeper bank verification, and most of the continuous red-flag types — is not yet built, either because it's blocked on a client decision (background-check provider) or hasn't been reached yet.

One bug and one missing feature were found and fixed this session: Plaid bank verification was silently failing for every customer (a database column was too narrow for the encrypted token), and the continuous risk red-flag list had never been wired up to anything at all. Both are now working and verified — see Section 2.

2. What's built and verified

- **Risk scoring on submission.** A 100-point score from identity, employment, bank, and background legs, each marked verified or pending.
Verified: score computed and displayed correctly on a live test application.
- **Apartment residences auto-decline.** Declined automatically before a reviewer ever sees it.
Verified: an apartment-residence test application was declined immediately on submission.
- **Affordability check.** An applicant whose reported income falls under the standard 3× monthly-payment ratio is flagged for review.
Verified: a test applicant reporting \$300/month income against a \$150/month payment was flagged, with the exact reasoning shown on the review screen.
- **Bank verification via Plaid.** Connection-level verification — confirming an account is linked.
Was silently broken for every customer; fixed this session. Verified: a full sandbox connection now completes and shows “verified” with a real timestamp.
- **Continuous red flags — three of eight types.** A failed payment, an overdue payment, and a customer reconnecting to a different bank account each now create a real, visible, resolvable flag on the admin review screen.
Built and verified this session — previously the red-flag table existed but nothing ever wrote to it.

3. What's not built yet

This is the honest gap list — none of it is broken, it's simply not reached yet or blocked on a decision outside the codebase.

Area	Current state	Status
Bank verification depth	Plaid confirms the account is linked and returns basic account info. Deposit history, pay frequency, overdraft patterns, and account age — all called for in the plan — are not pulled yet.	Not built
Identity verification	Self-reported — the government ID number and DOB are on file, not checked against a government ID service.	Not built

Employment verification	Self-reported — income and employment status are on file, not checked via pay stubs, employer contact, or bank deposits.	Not built
Background check	Provider not yet selected by the client (open item in the approved plan). Fraud/theft/prior-lease-to-own-default screening isn't connected.	Blocked on client
Red-flag coverage	failed_ach, missed_payment, and bank_account_change are live. unreachable_customer, suspicious_behavior, undisclosed_move, and a separate late_payment distinction have no signal in the app yet to trigger them.	Partially built
GPS anomaly tracking	Reserved in the schema; live GPS is a Phase 2 addition once the fleet grows, per the approved plan.	Phase 2 (by design)

4. Verified, not just built

1. An apartment-residence application is declined automatically, before it reaches a reviewer.
2. A low-income applicant is automatically flagged, with the reviewer able to see exactly why.
3. A real Plaid sandbox bank account connects successfully end to end, and the connection persists correctly in the database.
4. A failed payment, an overdue payment, and a changed bank account each create a real, visible, resolvable risk flag.

5. To reach completion

- Client to confirm which background-check provider to use (open item in the approved plan).
- Decide whether/when to connect a live identity-verification API, or keep self-reported for launch.
- Decide whether the four remaining red-flag types are needed for launch, or deferred — building detection for them (e.g. an “unreachable” marker, a move-notice flow) means new UI, not just backend wiring.
